

To perform the task in the nodes we use
ansible libraries known as modules.

← Modules

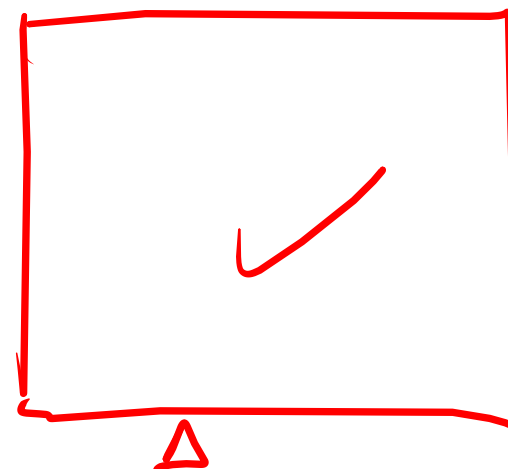

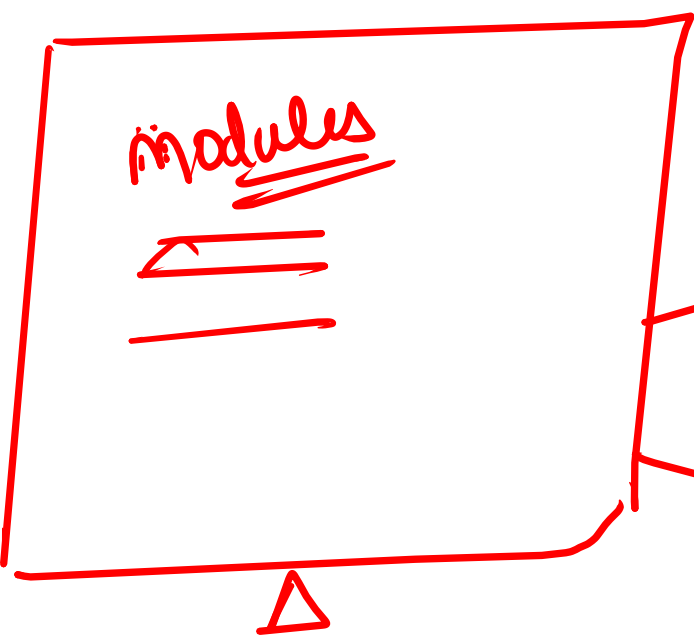

↙
ad hoc modules

single line commands

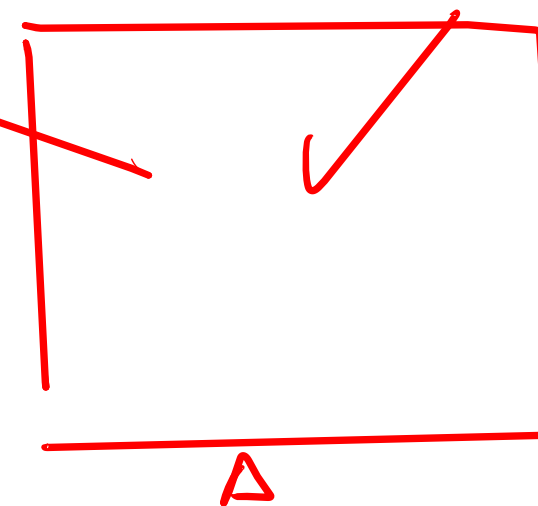

↘
Ansible playbook

we can write the list of modules
in the yaml file.

Ansible server

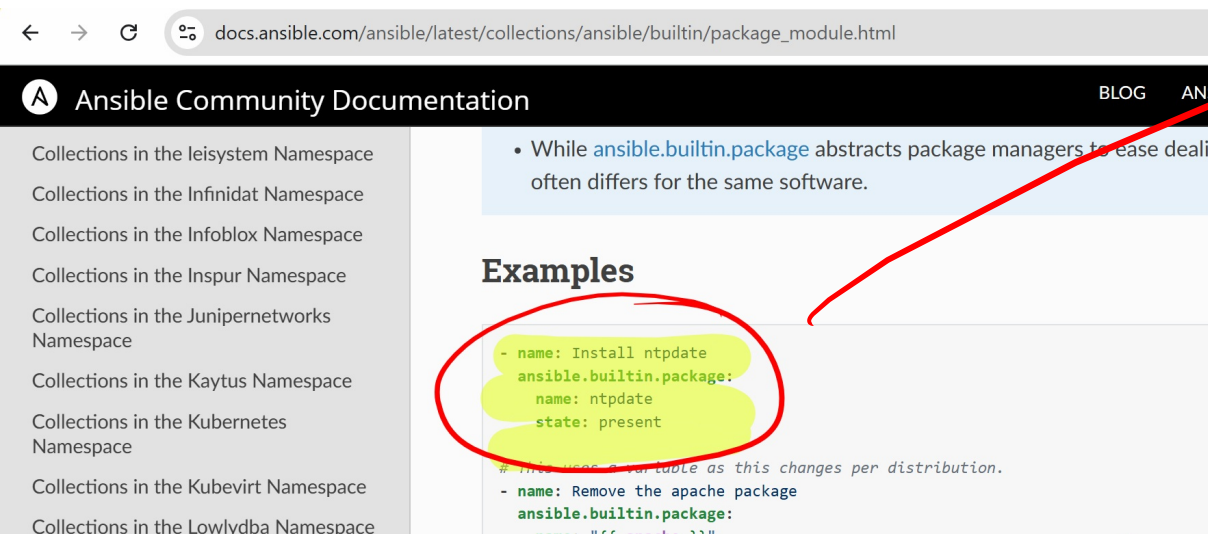

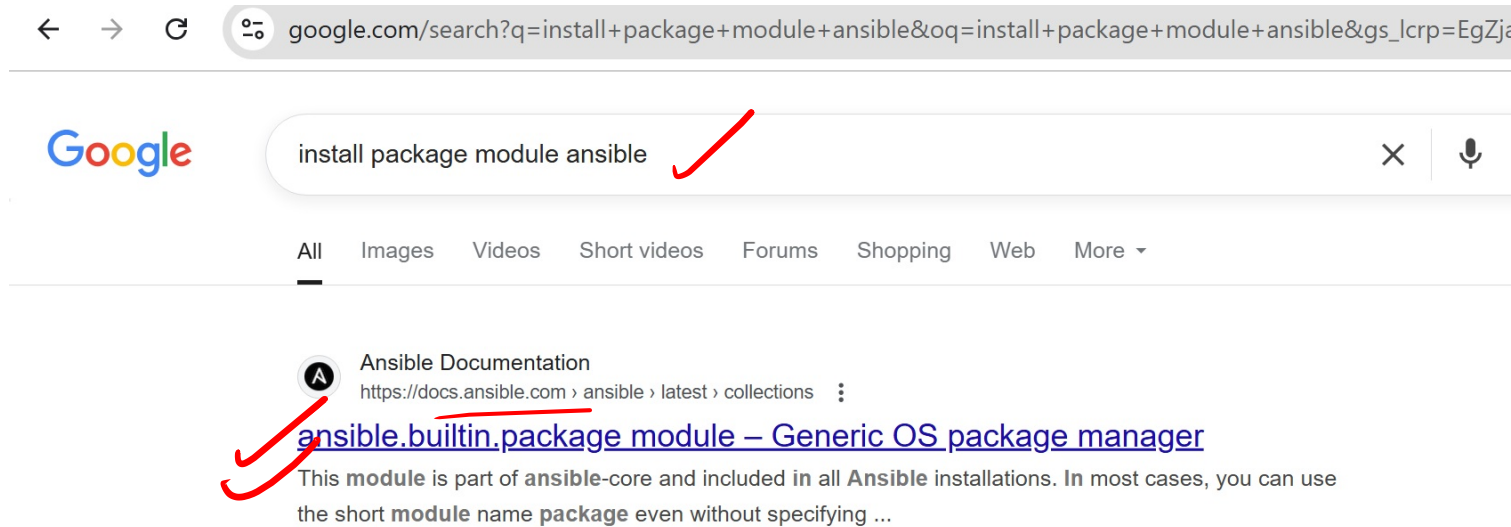

node 1

node 2

#lets say we need to install a package in the nodes

Using this example we need to write a single line ad hoc command to Install a package (e.g apache)

Examples

```
- name: Install ntpdate
ansible.builtin.package:
  name: ntpdate
  state: present
# This uses a variable as this changes per distribution.
- name: Remove the apache package
```

module name

argument

ansible all -b -m ansible.builtin.package -a "name=ntpdate state=present"

Package name

argument

module

become

This module
will be executed
with Root privilege

In all the nodes
(Here you put the
group as well)

present: Install
absent: delete
latest: update

module name

```
devops@ip-172-31-4-38:~$ ansible all -b -m ansible.builtin.package -a "name=apache2 state=present"
[WARNING]: Platform linux on host 172.31.2.64 is using the discovered Python interpreter at /usr/bin/python3.12, but future i
of another Python interpreter could change the meaning of that path. See https://docs.ansible.com/ansible-
core/2.18/reference_appendices/interpreter_discovery.html for more information.
